2021

## TIIVISTELMÄ

Tekijä	Teemu Kaarto
Opinnäytetyön nimi	Modbus to IEC 60870-5-104 Gateway Features, Programming and Performance
Vuosi	2021
Kieli	englanti
Sivumäärä	72 + 1 liite
Ohjaaja	Jari Koski

---

Opinnäytetyön tarkoituksena oli tutkia MGate 5114 Series gateway-laitteen yleisiä ominaisuuksia sekä kerätä yleistä tietoa energian lukumittareista. Opinnäytetyön tavoitteena oli löytää vastaus siihen, voisiko Hitachi ABB Power Grids Grid Automation-yksikkö mahdollisesti käyttää gateway-laitetta tulevaisuudessa infrastruktuurille suunnatuissa SCADA-projekteissa.

Tämä opinnäytetyö antaa kokonaiskuvan siitä, miten MGate konfiguroidaan käytännöllä siihen tarkoitettua työkalua. Opinnäytetyö antaa lisäksi käytännön esimerkin siitä, miten järjestelmä sulautetaan osaksi MicroSCADAa, sisältäen tietokannan sekä kommunikoinnin. Keskeisin menetelmä oli testaukseen perustuva menetelmä. Gateway-laitteen ominaisuuksia, kuten sen ohjelmointia ja suorituskykyä tutkittiin testiympäristössä.

Testitulosten perusteella voidaan todeta, että MGate sisältää tarvittavat ominaisuudet sekä vaadittavan suorituskyvyn, jotta se soveltuu käytettäväksi infrastruktuurille suunnatuissa SCADA-projekteissa tulevaisuudessa.

## ABSTRACT

Author	Teemu Kaarto
Title	Modbus to IEC 60870-5-104 Gateway Features, Programming and Performance
Year	2021
Language	English
Pages	72 + 1 Appendix
Name of Supervisor	Jari Koski

---

The purpose of the thesis was to examine the main features of the MGate 5114 Series gateway device and to collect a wide set of information of the energy metering application. The aim of the thesis was to find the answer to the question whether Hitachi ABB Power Grids Grid Automation unit could possibly use the gateway device in the future in its infrastructure SCADA projects.

This thesis gives an overall picture of how to configure the MGate by using the dedicated tool and a practical example of how to establish the system with MicroSCADA, including database and communication. A test-based method was the main method used in this thesis. The device main features including programming and performance were targets to be evaluated and documented in a test environment.

Based on the testing results, the MGate have the reasonable features and demanding performance so that it can be used in future infrastructure SCADA projects.

Modbus RTU	Modbus protocol that is used in serial communication
Modbus TCP	Modbus protocol that is used for communication over TCP/IP networks
M4M 20	ABB's Network analyzer
NTP	Network Time Protocol
OID	Object Identifier
OPCS1	OPC Server for SNMP
PC	Personal Computer
Quick Setup	Moxa's configuration tool
RTU	Remote Terminal Unit
UART	Universal Asynchronous Receiver Transmitter
TCP	Transmission Control Protocol
MicroSCADA Pro	Hitachi ABB Power Grids product family for substation and network control system
RTS	Request To Send
RS-485	Interface, defined by the EIA/TIA standard

RTU	Remote Terminal Unit
Rx signal	Receive signal
SCADA	Supervisory Control and Data Acquisition
SCS	Substation Control System
SCIL	Supervisory Control Implementation Language
SPS	Single Point Status
STA object	Station object
SNMP	Simple Network Management Protocol
SnmpB	Open-source SNMP MIB browser
Sverker 750	Single-phase relay tester
Walk function	Can be used to walk through a directory tree and find the data
WAN	Wide Area Network
Web console	A web-based application that allows end-users to manage their data
Wireshark	Network protocol analyzer

## 1 INTRODUCTION

The purpose of this thesis was to examine the Moxa MGate 5114 Series gateway device and to find out more information about the energy metering application. This thesis was done for Hitachi ABB Power Grids Grid Automation unit. The aim of the thesis was to find out the answer to the question whether MGate have the reasonable features and the needed performance so that it can be used in infrastructure SCADA projects.

Usually there are several alternatives to collect data from energy meters to the MicroSCADA. In a MicroSCADA based system, simple and hierarchic data collection is the most suitable solution with high performance and reliability. A typical protocol in the energy meter device is Modbus RTU or Modbus TCP. One new alternative is to use Modbus to IEC 60870-5-104 gateway devices. The Moxa is one of the most well-known manufactures for such a gateway device as the MGate 5114 Series. According to the marketing material and base clarifications, it should have reasonable features. Also, ABB Power Grids Finland has a long experience in working with the manufacturer. The used gateway device during the test part of this thesis was provided by Suomen Addon Oy.

A test-based method was used in this thesis. The MGate main features including the programming and performance were targets to be evaluated and documented in a test environment. The practical target for the thesis was to establish the system with MicroSCADA, including the database and communication.

## **2 HITACHI ABB POWER GRIDS**

In 2020, Hitachi and ABB's Power Grids' business came together in a joint venture. Together, as Hitachi ABB Power Grids, it is a new global leader with a combined heritage of almost 250 years. The company is headquartered in Switzerland and employs around 36,000 people in 90 countries. The business serves utility, industry and infrastructure customers across the value chain and emerging areas, such as cities, energy storage systems and data centers. /1-2/

### **2.1 Grid Automation**

Hitachi ABB Power Grids in Finland is divided into the three main business units, which are Grid Automation, Grid Integration and Transformers. The Grid Automation unit provides systems for electric utilities and industry. Project management, engineering, commissioning, substations gateways, transmission and distribution network solutions, such as substations for energy and electricity companies are included in their line of business. The main market areas are Finland, Northern Europe and Middle East. /3-4/

### 3 THEORETICAL BACKGROUND

A typical MGate 5114 Series application consists of a SCADA as a client/master and a field device as a server/slave. These components use different kinds of protocols and thus there is a need to use a gateway device in between to exchange data. A field device during the test part of this thesis was a M4M 20 Network analyzer. /5-6/

#### 3.1 MGate 5114 Series

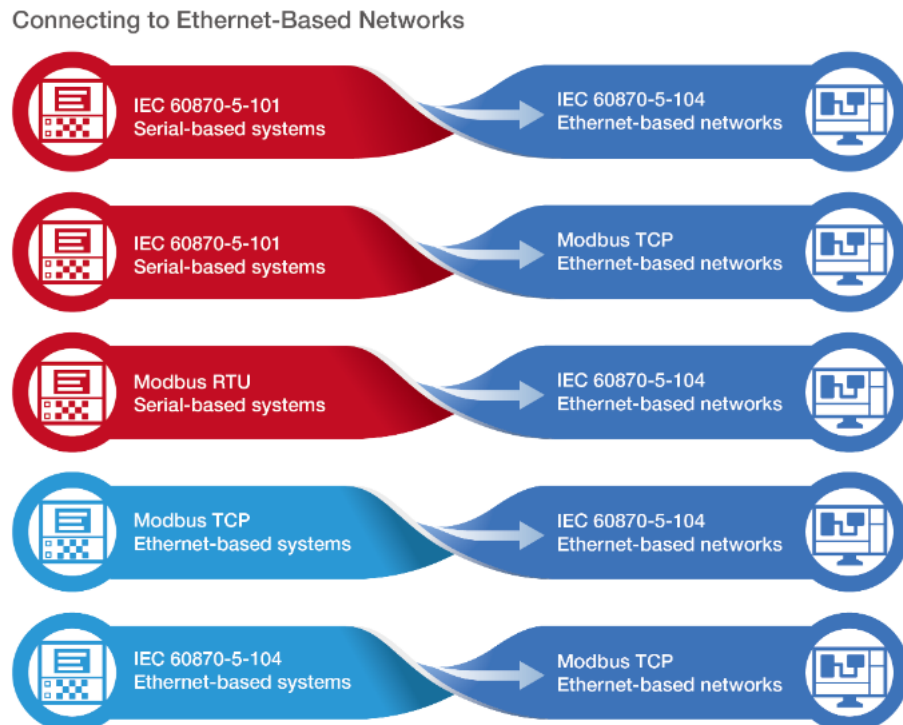

As shown in Figure 1, the MGate 5114 Series is Moxa's industrial Ethernet gateway device with 2 Ethernet ports, 1 console port and 1 serial port. The MGate provides the needed flexibility to fulfill the conditions that arise with field devices that use different communications protocols. The gateway device provides multiple conversion options between the different gateways, thereby fulfilling a wide variety of different requirements. The different variations when connecting to Ethernet-based networks can be seen in Figure 2. /5-6/

**Figure 1.** MGate 5114 Series. /5/

The main features of the gateway device are:

- Redundant dual DC power inputs and one relay output
- Designed to be attached to a DIN rail or mounted on a wall
- Equipped with a microSD card slot
- Possibility to apply the same configuration to the multiple units by using the configuration import and export function
- Easy configuration via a user-friendly web console
- Step-by-step configuration guide with Quick Setup
- Complete packet analysis and diagnostic information for maintenance and troubleshooting
- Embedded Modbus RTU/ASCII and IEC 60870-5-104 traffic monitoring
- Possible to restore the factory default setting by using the reset button
- Security features based on IEC 62443 standards. /5-6/

**Figure 2.** Different variations when connecting Ethernet-based networks.  
/7/

Before the test part of the thesis, the DIP switch number 3 in MGate was adjusted. The DIP switch needed to be adjusted to minimize the reflections from the end of the RS-485 serial cable. It is possible to adjust DIP switches after removing the MGate's top cover, as seen in Figure 3.

**Figure 3.** DIP switches in MGate.

During the tests the switch 3 was in position on and then the terminator value was 120  $\Omega$ . Each position specific explanation can be seen in Table 1.

**Table 1.** DIP switches possible positions. /6/

SW	1	2	3
	Pull-high resistor	Pull-low resistor	Terminator
ON	1 k $\Omega$	1 k $\Omega$	120 $\Omega$
OFF	150 k $\Omega$ *	150 k $\Omega$ *	-*

\*Default

### 3.2 M4M 20 Network Analyzer

M4M 20 is ABB's Network analyzer that allow accurate real-time energy data monitoring. The picture of the M4M 20 can be seen in Figure 4. The used analyzers during the test part of this thesis were provided with Modbus RTU communication, which means that they were equipped with RS-485 port. The RS-485 terminal was a 3-pole plug contact. Figure 5 presents the principle of how to wire RS-485 serial cable on M4M 20. /8-9/

**Figure 4.** M4M 20 Network analyzer. /8/

**Figure 5.** RS-485 wiring on M4M 20 Network analyzer. /9/

A and B are mandatory for the correct communication of the device. C can be connected to the data common ground if it is available and needed. RS-485 is a differential signal so common ground is not mandatory to use. A differential signal means that the signal is the difference between the A and B voltages. The third wire C, is also known as a common wire, is used to ensure that the common mode requirements from -7 V to +12 V of the transceivers are maintained. /9/

The M4M 20 can be used in different types of network. According to the type of the used network, the parameters visualized on the M4M 20 HMI change. The principle of the used wiring diagram during the tests was 1-phase 2 wire network with 1 current transformer, as shown in Figure 6. /10/

**Figure 6.** 1-phase 2 wire network with 1 current transformer. /10/

The Modbus RTU communication is based on the master-slave architecture. Usually the Modbus RTU message consists of the slave address, the function code, the actual data, which depends on the function code and the CRC of the checksum. The function code will tell the slave device what kind of action to perform. The function codes are used to read or write 16 bits (2 bytes) registers. Metering data, such as voltage, current or active energy are represented by one or more such registers. The following function codes were supported in M4M 20:

- Function code 3 (Read holding registers)
- Function code 6 (Write single register)
- Function code 16 (Write multiple register). /9/

The messages can be query-response or broadcast type. The used type of the message was the query-response-type command during the tests. It sends a query from the master to individual slave and is generally followed by a response, whereas the broadcast command sends a message to slave and is never followed by a response. Therefore, it is recommended that the user reads the value to confirm the result after the set value has set in the energy meter. This type of command is supported by function code 6 and 16. /9/

## **4 MGATE 5114 SERIES PROGRAMMING AND PERFORMANCE**

A test-based method was used in this thesis. The main features of the Moxa MGate 5114 Series gateway device, including the programming and performance, were targets to be evaluated and documented in a test environment. The MGate programming was done by using the Moxa dedicated tool. The dedicated tool was a user-friendly web console and automated technologies including the Quick Setup configuration tool that allowed to configure the gateway device.

The test set-up consisted of the following devices: MGate 5114 Series gateway device, two M4M 20 Network analyzers, two CT PRO XT current transformers, AF675 switch, Sverker 750, different gateways and PC, which runs Microsoft Hyper-V virtual machine. A RS-485 serial cable was used to connect the MGate to the Modbus RTU slave devices. The CAT 6 Ethernet cable was connected between the MGate and IEC 60870-5-104 master device, via the AFS675. The picture of the test-set up can be seen in Appendix 1.

The MGate role 1 was IEC 60870-5-104 slave. MicroSCADA was used as an IEC 60870-5-104 master to monitor the Modbus RTU slave devices. It was possible to integrate the existing Modbus RTU slave devices into IEC 60870-5-104 network, when the MGate role 2 was a Modbus RTU master. The MGate collected the data from the Modbus RTU slave devices and exchanged it with IEC 60870-5-104 system. Figure 7 presents the principle of the system topology.

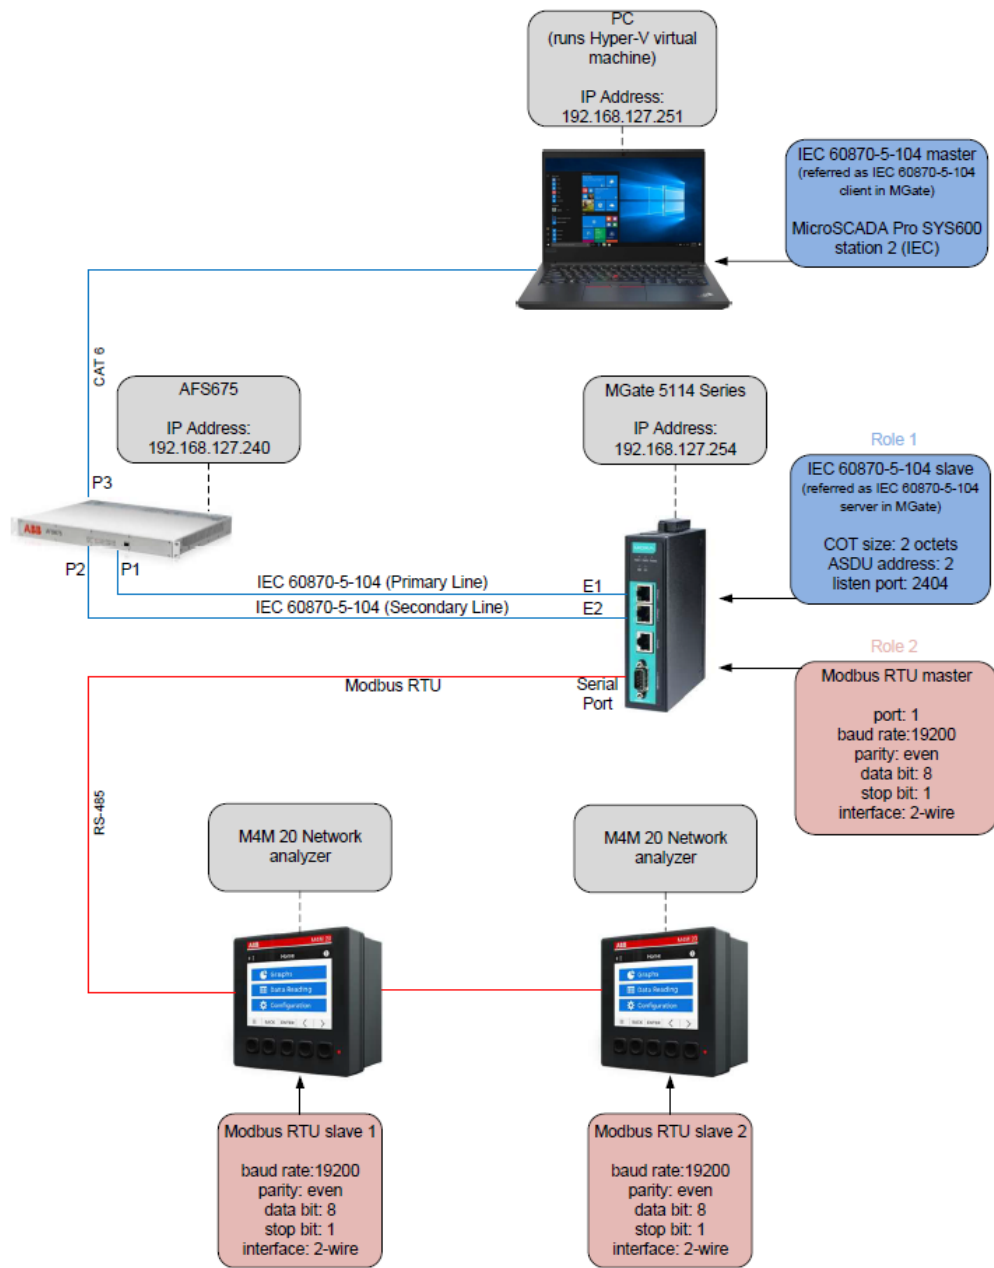

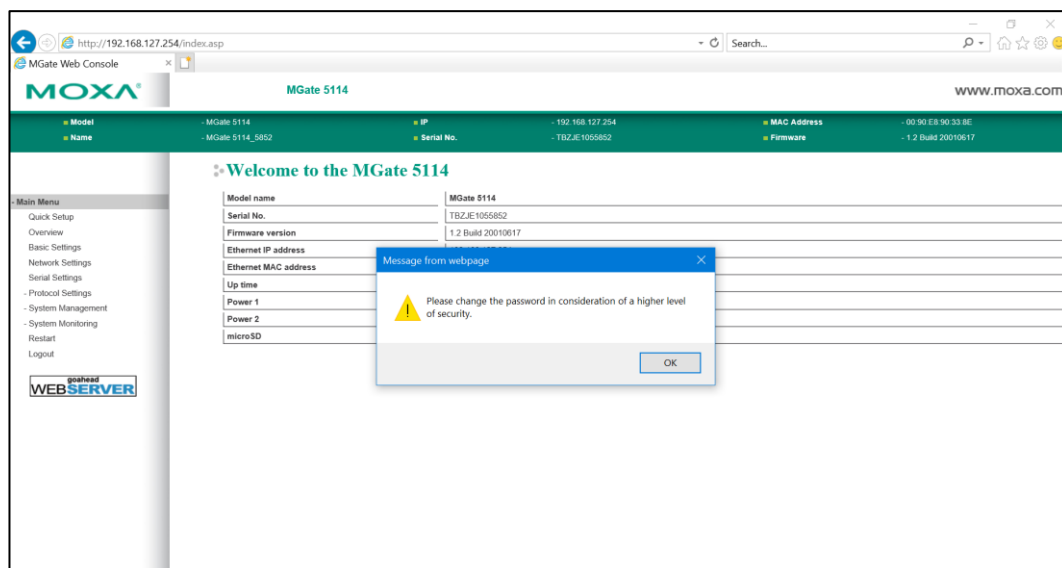

Figure 7. The principle of the system topology.

#### 4.1 Basic Settings Configuration

Before the use of the Quick Setup configuration tool, the basic settings of the gateway device needed to be configured, including also network and serial settings configurations. The web console was used to configure the MGate through the Ethernet. A web browser such as Microsoft Internet Explorer or Google Chrome are suitable, when using the HTTP/HTTPS protocol. The MGate's default IP address was 192.168.127.254. /6/

It was also possible to detect the MGate by using the DSU software. It can be used in case the user does not know the MGate's IP address. The software can be downloaded from Moxa's website. /6/

The first time, when logging up in the web console, the default settings were used. The default account name was admin and the default password was moxa. After a successful logging-in the warning message from the webpage popped out, as presented in Figure 8. /6/

**Figure 8.** The warning message from webpage.

The new account and password were created by emphasizing a higher security level. The password can be changed by following the path: System Management > Miscellaneous Settings > Account Management.

As shown in Figure 9, the Basic, Network and Serial Settings were under the Main Menu header.

Welcome to the MGate 5114	
Model name	MGate 5114
Serial No.	TBZJE1055852
Firmware version	1.2 Build 20010617
Ethernet IP address	192.168.127.254
Ethernet MAC address	00:90:E8:90:33:8E
Up time	0 days 00h:04m:23s
Power 1	On
Power 2	Off
microSD	In Use

**Figure 9.** Main Menu.

Figure 10 presents how the server and time settings were configured. The server name can be given to help the user to identify the unit, such as its function if there are several similar units in use. The server name was MGate\_5114\_Test. Server location identifies the unit currently location, which was named as FAT-area\_Vaasa. /6/

After the server settings were configured, the time settings needed to be configured, as well. The MGate has a built-in real-time clock for time calibrations functions. The functions such as log function can add a real-time information to the message. It is also worth to mention that the first-time users should select the time zone first, thus the console displays the “the real-time” according to the time zone relative to GMT. The user adjustable time can be changed by selecting the local time. The user can select the way how the time synchronization is done by selecting parameter time source. It can be NTP or Protocol. If the NTP is selected,

the time server can be an IP or Domain address. During the test part of the thesis time source was protocol and the time zone was (GMT+02:00) Helsinki, Riga, Sofia, Tallinn. /6/

The screenshot shows a web interface titled "Basic Settings". It is divided into two main sections: "Server Settings" and "Time Settings".

**Server Settings:**

- Server name:** MGate\_5114\_Test
- Server location:** FAT-area\_Vaasa

**Time Settings:**

- Time zone:** (GMT+02:00)Helsinki, Riga, Sofia, Tallinn
- Local time:** 2021 / 01 / 25 09 : 55 : 06
- Time source:** Protocol
- Time server:** (empty text box)

A "Submit" button is located at the bottom center of the form.

**Figure 10.** Basic Settings.

Figure 11 presents the Network Settings webpage where it was possible to modify the unit's network parameters. Parameter IP configuration can have a value Static, DHCP or BOOTP. The Static IP address was in use during the tests and it means that the IP address does not change. The other options should be selected if the IP address is set dynamically. The IP address identifies the server on the TCP/IP network. The used IP address was the same as the earlier mentioned gateway device default IP address. The netmask identifies the server as belonging to a Class A, B or C network. Class C network was used this time. The gateway IP address was 192.168.127.1 and it is the IP address of the router that provides the network access outside the server LAN. Parameter DNS server 1 is the primary domain, whereas DNS server 2 is the secondary domain server. Neither of the DNS servers were in use and therefore these rows were left blank. /6/

## Network Settings

Network Settings

IP configuration Static

IP address

Netmask

Gateway

DNS server 1

DNS server 2

**Figure 11.** Network Settings.

The following serial settings, which can be seen in Figure 12, were configured to be the same in the MGate and Modbus RTU slave devices. MGate's serial interface supports RS-232, RS-422 and RS-485 interfaces. Disabling the FIFO can reduce the latency time, when receiving the data from serial communications. FIFO means the internal buffer memory of UART. The RTS toggle function was available for RS-232 mode only. /6/

## Serial Settings

Port	Baud rate	Parity	Data bit	Stop bit	Flow control	FIFO	Interface	RTS on delay	RTS off delay
1	19200	Even	8	1	None	Enable	RS-485 2-wire	0	0

**Figure 12.** Serial Settings.

## 4.2 Quick Setup Programming

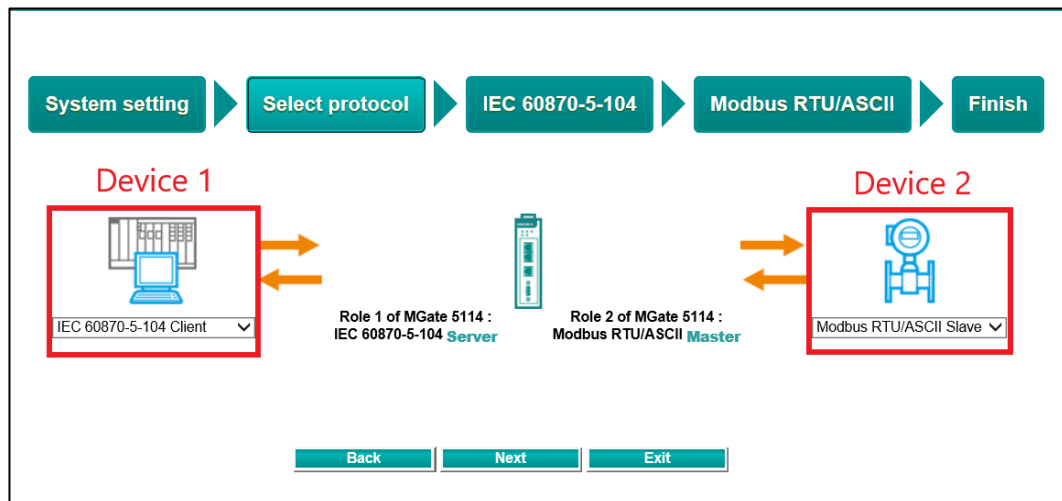

This section gives an example of how to program the MGate by using the Quick Setup configuration tool. Quick Setup is an illustrated guide which is designed to make the configuration process easy. It takes the user through the configuration process from the start to the end. The MGate's performance when reading single Modbus registers was tested after the Quick Setup configurations were done. /6/

As seen in Figure 13, the server and network settings were first configured in System setting window. These settings were only checked that they were the same ones as earlier parameterized.

The screenshot displays the 'System setting' window of the Quick Setup tool. At the top, a progress bar shows the steps: System setting, Select protocol, IEC 60870-5-104, Modbus RTU/ASCII, and Finish. The 'System setting' step is currently active. On the left, a 'Main Menu' sidebar lists options like Quick Setup, Overview, Basic Settings, Network Settings, Serial Settings, Protocol Settings, System Management, System Monitoring, Restart, and Logout. The 'goahead WEB SERVER' logo is visible at the bottom left. The main configuration area is divided into 'Server Settings' and 'Network Settings'. Under 'Server Settings', the 'Server name' field contains 'MGate\_5114\_Test'. Under 'Network Settings', the 'IP configuration' is set to 'Static'. The 'IP address' field contains '192.168.127.254', the 'Netmask' field contains '255.255.255.0', and the 'Gateway' field contains '192.168.1.1'. 'Next' and 'Exit' buttons are located at the bottom right.

**Figure 13.** System setting (Quick Setup).

Figure 14 shows the Select protocol webpage, where the gateway device protocols on each side were selected. If the device 1, in this case the PC, is set as IEC 60870-5-104 client, then the MGate automatically configured the IEC 60870-5-104 server side by using the default settings. Table 2 shows the possible device 1 and 2 roles in MGate.

**Figure 14.** Select protocol (Quick Setup).

**Table 2.** Device 1 and 2 possible roles in MGate.

Device 1	Device 2
IEC 60870-5-104 Client	Modbus RTU/ASCII Slave
IEC 60870-5-104 Client	Modbus TCP Server
IEC 60870-5-104 Client	IEC 60870-5-101 Slave
IEC 60870-5-101 Master	Modbus TCP Server
IEC 60870-5-101 Master	IEC 60870-5-104 Server
Modbus TCP Client	IEC 60870-5-101 Slave
Modbus TCP Client	IEC 60870-5-104 Server
Modbus RTU/ASCII Master	IEC 60870-5-104 Server

On the IEC 60870-5-104 slave side, there were both the basic and advanced settings. As seen in Figure 15, only the basic settings were possible to configure during the Quick Setup process. The ASDU address was changed from default value 3 to the value 2. Otherwise the basic settings were the default ones.

System setting → Select protocol → IEC 60870-5-104 → Modbus RTU/ASCII → Finish

Your device : IEC 60870-5-104 Client      Role 1 of MGate 5114 : IEC 60870-5-104 Server      Role 2 of MGate 5114 : Modbus RTU/ASCII Master      Your device : Modbus RTU/ASCII Slave

Mode selection      Slave

Basic Settings

ASDU address       (1 - 65534)

Listen port       (1024 - 60000)

Back      Next      Exit

**Figure 15.** IEC 60870-5-104 (Quick Setup).

On the Modbus RTU/ASCII webpage the mode was selected as Modbus RTU and the serial settings were the same ones as configured in Chapter 4.1 Basic Settings Configuration. The function code 3 was used to read measurement value phase voltage L1 from the M4M 20 Network analyzer slave 1 and slave 2. The Modbus command was first created for slave number 1. As seen in Figure 16, the first created Modbus command was copied to the slave 2 by using the clone function.

The screenshot shows a configuration interface for Modbus RTU/ASCII. A dialog box is overlaid on top, asking to 'Set slave ID range to copy' with the value '2' entered. The background shows the main configuration screen with various settings like Modbus Mode, Serial Parameter Settings, and Modbus Commands.

**System setting** **Select protocol**

Set slave ID range to copy :  (ex : 1,2,3-5)

**OK** **Cancel**

**Figure 16.** Modbus RTU/ASCII (Quick Setup).

Once all the configurations in Quick Setup were done, it was checked whether the parameters were the same as configured earlier. The Finish webpage shows a summary of the configurations, as seen in Figure 17. The Quick Setup process was finalized by clicking the 'save' button.

**Figure 17.** Finish (Quick Setup).

It was possible to view IEC 60870-5-104 and Modbus RTU mapping status by following the path: Protocol Settings > I/O Data Mapping. In this table it was meant to check that all object points were mapped correctly. There were two possible dataflow directions. The possible directions were read and written. In Figure 18 can be seen that, for instance the Modbus RTU master sends read "Phase voltage L1" command to Modbus RTU slave 2. The internal address area was then 4-7 on both sides of the MGate. The used object data type was the measured value normalized. The Quick Setup tool uses this type of object data type by default. After the mapping address arrangement was set from automatic to manual, it was possible to adjust internal addresses. In this case only the automatic mapping address arrangement was used.

### Data Mapping

Data flow direction: IEC 60870-5-104 Client ← Modbus RTU/ASCII Slave

Mapping address arrangement: Automatic

Your device :  
IEC 60870-5-104 Client

**Role 1 of MGate 5114 :**  
IEC 60870-5-104 **Server**

**Role 2 of MGate 5114 :**  
Modbus RTU/ASCII **Master**

Your device :  
Modbus RTU/ASCII Slave

Type	IOA	Internal Address	Data Size	Name	Function	Internal Address	Quantity
Measured value(Normalized) (value) 1 - 2	0	3	4 bytes	Phase voltage L1	3	0...3	4 bytes
Measured value(Normalized) (value) 3 - 4	4	7	4 bytes	Phase voltage L1	3	4...7	4 bytes

**Submit**

**Figure 18.** Data Mapping.

As seen in Figure 19, the Modbus RTU/ASCII Traffic webpage provided a traffic monitoring function, which captured the Modbus RTU communication logs. This webpage can be found by following the path: System Monitoring > Protocol Status > Modbus RTU/ASCII Traffic.

### Modbus RTU/ASCII Traffic

13	3.473	Send	1	3	01 03 5B 02 00 02 76 EF
14	3.509	Receive	1	3	01 03 04 00 00 01 F9 3B E1
15	3.632	Send	2	3	02 03 5B 02 00 02 76 DC
16	3.673	Receive	2	3	02 03 04 00 00 01 FA 48 E0

**Figure 19.** Modbus RTU/ASCII Traffic.

The actions number 15 and 16 are explained in Tables 3 and 4.

**Table 3.** Send frame.

Parameter	Hex
Slave address	0x02
Function code	0x03
Start address, high byte	0x5B
Start address, low byte	0x02
Number of registers, high byte	0x00
Number of registers, low byte	0x02
Error check (CRC), high byte	0x76
Error check (CRC), low byte	0xDC

**Table 4.** Receive frame.

Parameter	Hex
Slave address	0x02
Function code	0x03
Byte count	0x04
Value of register 0x5B02, high byte	0x00
Value of register 0x5B02, low byte	0x00
Value of register 0x5B03, high byte	0x01
Value of register 0x5B03, low byte	0xFA
Error check (CRC), high byte	0x48
Error check (CRC), low byte	0xE0

As Table 4 presents, the value of the register 0x5B03 was 01FA in hexadecimal, so it needed to be converted to decimals. In decimals the value was 506. The resolution was 0,1 according to ABB's M4M Modbus mapping table, so the value needed to be multiplied by 0,1 /11/. The result after the multiplication was then 50,6 Volts. Then the phase voltage L1 measurement value was checked from M4M 20 Network analyzer slave 2. The value was 50,562 Volts. As a conclusion we can state that MGate's performance is reliable when reading single Modbus registers.

### 4.3 Establishing the System with MicroSCADA

The practical aim of the thesis was to establish the system with MicroSCADA, including database and communication. The used version was MicroSCADA Pro SYS600 9.4 FP2 HF3 and it was installed in Microsoft Hyper-V virtual machine.

#### 4.3.1 MGate 5114 Series Configuration

This section gives an example of the MGate's configurations when reading multiple Modbus registers. The configuration of the MGate was done by using the earlier introduced Quick Setup configuration tool. This time some of the master and advanced settings also needed to be adjusted. These settings can be adjusted when the Quick Setup process is finished.

The Modbus mode and serial settings were the same ones as earlier configured in Chapter 4.2 Quick Setup Programming. Figure 20 presents the Modbus RTU/ASCII Master webpage, where the master settings were adjusted. For example, the MGate was forced to wait 200 milliseconds before sending the first request with the initial delay parameter. The maximum polling retry value was 1 and it is the adjusted number of times the master will retry the same request when the response times out. The response timeout was 5000 milliseconds and based on this response time, the master was configured to wait a certain amount of time for the slave's response. This allows the Modbus system to continue operations even if a slave device is disconnected or faulty. /6/

The endian swap parameter can be configured either the Modbus RTU master side or the IEC 60870-5-104 server side. The value byte is suitable for most scenarios. The created Modbus commands are shown in Figure 21. /6/

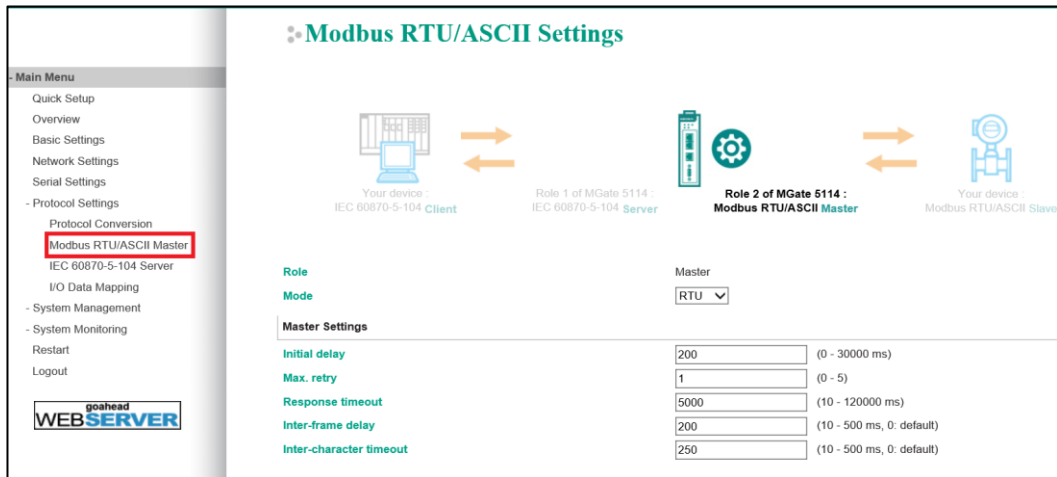

Figure 20. Modbus RTU/ASCII Master (Master Settings).

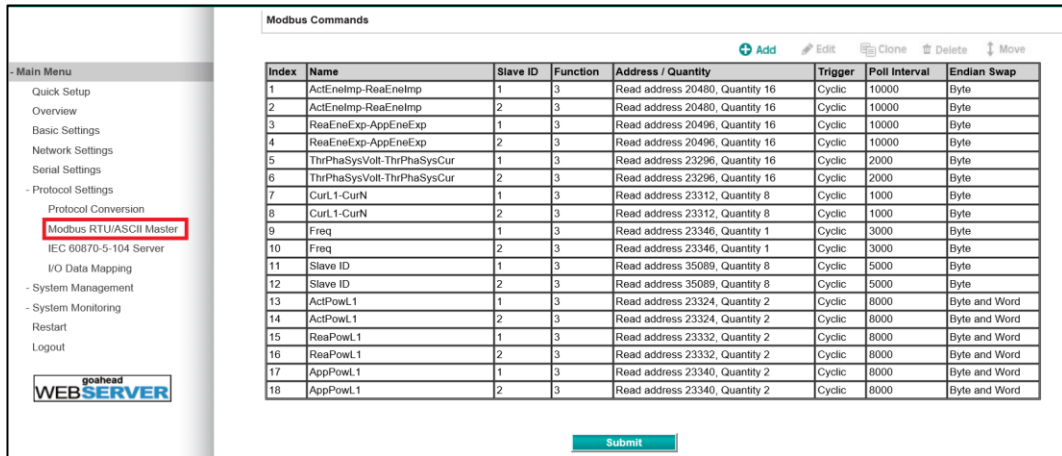

Figure 21. Modbus RTU/ASCII Master (Modbus Commands).

Table 5 shows the detailed explanation of index 1 addresses.

**Table 5.** Index 1 addresses explained.

Parameter	Data Type	Access	Start Register (Hex)	Start Register (Dec)	Read Quantity	Quantity in Bytes
Active energy - import	Unsigned	Read	5000	20480	1	2
	Unsigned	Read	5001	20481	1	2
	Unsigned	Read	5002	20482	1	2
Active energy - export	Unsigned	Read	5003	20483	1	2
	Unsigned	Read	5004	20484	1	2
	Unsigned	Read	5005	20485	1	2
Active energy - net	Unsigned	Read	5006	20486	1	2
	Unsigned	Read	5007	20487	1	2
	Signed	Read	5008	20488	1	2
Reactive energy - import	Signed	Read	5009	20489	1	2
	Signed	Read	500A	20490	1	2
	Signed	Read	500B	20491	1	2
Total	Unsigned	Read	500C	20492	1	2
	Unsigned	Read	500D	20493	1	2
	Unsigned	Read	500E	20494	1	2
	Unsigned	Read	500F	20495	1	2
Total	-	-	-	-	16	32

Figure 22 shows the IEC 60870-5-104 Server webpage where the advanced settings were possible to configure. The basic settings were the same ones as earlier configured in Chapter 4.2 Quick Setup Programming. For instance, the timestamp reference was set as local time, measured value spontaneous feature was enabled, cyclic interval value of the measured valued (scaled) was set as 60 seconds and point status value was 100 seconds. The parameter point status timeout is a critical in case of possible fault situations of the slave device. Its purpose is to check the MGate's internal memory to see if the object status updates periodically. /6/

Parameter	Value	Range / Unit
k	12	(1 - 32)
w	8	(1 - 32)
T1 timeout	15000	(1 - 3000000 ms)
T2 timeout	10000	(1 - 3000000 ms)
T3 timeout	20000	(1 - 172800000 ms)
Timestamp reference	Local Time	
Enable cse active termination	Enable	
Enable cmd active termination	Enable	
Select timeout (Select/Execute)	320	(0 - 600 s, 0 for executing only)
General interrogation timestamp format	56bits	
Event timestamp format	56bits	
Measured value cyclic timestamp format	56bits	
Measured value spontaneous	Enable	
Measured value(Normalized) cyclic interval	0	(0 - 2073600 s, 0 for disable)
Measured value(Scaled) cyclic interval	60	(0 - 2073600 s, 0 for disable)
Measured value(Floating) cyclic interval	0	(0 - 2073600 s, 0 for disable)
Point status timeout	100	(5 - 3600 s, 0 for disable)
Endian swap	None	

**Figure 22.** IEC 60870-5-104 Server (Advanced Settings).

The possible data object types and address areas in MGate are:

- Single point
- Double point
- Step position
- Bitstring of 32 bit
- Measured value Normalized (0-65535)
- Measured value Scaled (0-65535)
- Measured value Floating (0-100000000)
- Integrated totals. /6/

The data object type should be selected so that the address area of the data object is not exceeded. The used point settings can be seen in Figure 23.

Index	Memory Access	Object Type	IOA
1	Read	Write	Measured value(Scaled)
2	Read	Write	Measured value(Scaled)
3	Read	Write	Measured value(Scaled)
4	Read	Write	Measured value(Scaled)
5	Read	Write	Measured value(Scaled)
6	Read	Write	Measured value(Scaled)
7	Read	Write	Measured value(Scaled)
8	Read	Write	Measured value(Scaled)
9	Read	Write	Measured value(Scaled)
10	Read	Write	Measured value(Scaled)
11	Read	Write	Measured value(Scaled)
12	Read	Write	Measured value(Scaled)
13	Read	Write	Integrated totals
14	Read	Write	Integrated totals
15	Read	Write	Integrated totals
16	Read	Write	Integrated totals
17	Read	Write	Integrated totals
18	Read	Write	Integrated totals

**Figure 23.** IEC 60870-5-104 Server (Point Settings).

Index numbers 13, 15 and 17 were requested by group 1 counter request, whereas the index numbers 14, 16 and 18 were requested by group 2 counter request. Figure 24 presents the index 13 configurations.

Index	Memory Access	Object Type	IOA
1	Read	Write	Measured value(Scaled)
2	Read	Write	Measured value(Scaled)
3	Read	Write	Measured value(Scaled)
4			
5			
6			
7			
8			
9			
10			
11			
12	Read	Write	Measured value(Scaled)
13	Read	Write	Integrated totals
14	Read	Write	Integrated totals
15	Read	Write	Integrated totals
16	Read	Write	Integrated totals
17	Read	Write	Integrated totals
18	Read	Write	Integrated totals

**Figure 24.** IEC 60870-5-104 Server (Index 13).

It is worth to mention that the integrated totals data object type acts as a counter. The IOA addresses of these kinds of data object types can be double-checked by using the later introduced IEC 60870-5-104 Server Diagnostics tool in cases it seems that the IOA addresses are different than what the data mapping table gives. In this case the IOA addresses of the integrated totals were mapped by using the automatic arrangement tool. The addresses of the integrated totals data object types were different than the table gives and thus the diagnostics tool was

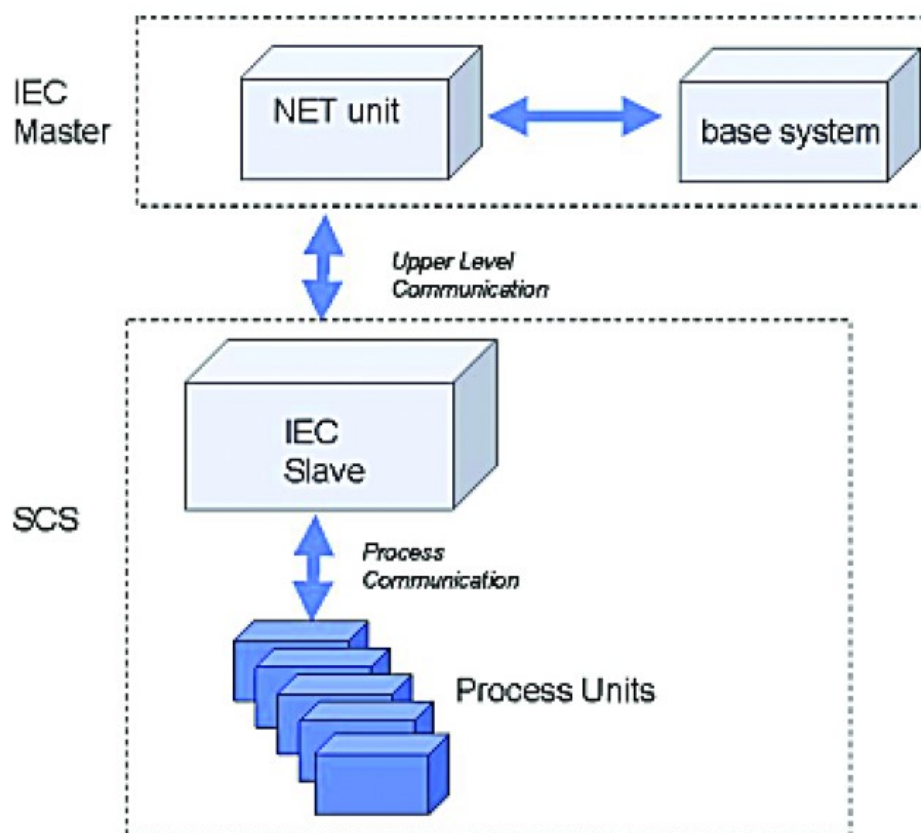

used to find the right addresses. The used data mapping table can be seen in Figure 25. /6/

Type	IOA	Internal Address	Data Size	Name	Function	Internal Address	Quantity
Measured value(Scaled) (value)	1 - 16	0 .. 31	32 bytes	ActEnelmp-ReaEnelmp	3	0 .. 31	32 bytes
Measured value(Scaled) (value)	17 - 32	32 .. 63	32 bytes	ActEnelmp-ReaEnelmp	3	32 .. 63	32 bytes
Measured value(Scaled) (value)	33 - 48	64 .. 95	32 bytes	ReaEneExp-AppEneExp	3	64 .. 95	32 bytes
Measured value(Scaled) (value)	49 - 64	96 .. 127	32 bytes	ReaEneExp-AppEneExp	3	96 .. 127	32 bytes
Measured value(Scaled) (value)	65 - 80	128 .. 159	32 bytes	ThrPhaSysVolt-ThrPhaSysCur	3	128 .. 159	32 bytes
Measured value(Scaled) (value)	81 - 96	160 .. 191	32 bytes	ThrPhaSysVolt-ThrPhaSysCur	3	160 .. 191	32 bytes
Measured value(Scaled) (value)	97 - 104	192 .. 207	16 bytes	CurL1-CurN	3	192 .. 207	16 bytes

Figure 25. I/O Data Mapping.

### 4.3.2 SYS600 Base and Communication System Configuration

The IEC 60870-5-104 master protocol is used in LAN and WAN networks to connect central stations and substations to each other. In MicroSCADA the IEC 60870-5-104 master protocol uses the Ethernet connection, whereas the IEC 60870-5-104 slave communicates with a master using the TCP/IP. Figure 26 shows an example of how the IEC master sees the SCS as an IEC slave. /12/

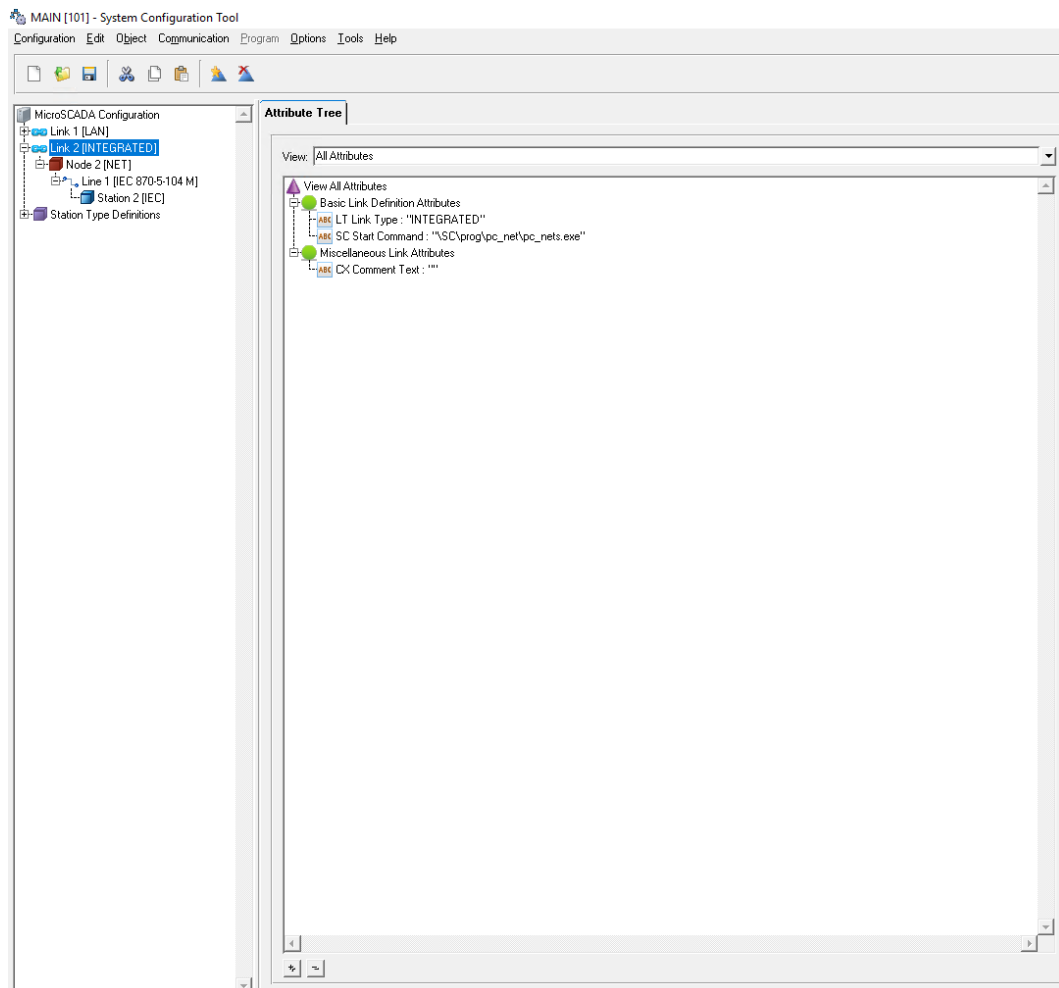

**Figure 26.** The communication between SYS600 and SCS. /12/

In SCADA, the base system and the communication system was configured to establish communication to the IEC 60870-5-104 slave device. The configuration was made by using the System Configuration Tool. The configuration in SYS600 can be divided into two parts:

- Base system configuration
- Communication system configuration. /12/

In SYS600 the IEC 60870-5-104 master protocol is implemented in the PC-NET software. This means that the PC-NET unit communicates over an INTEGRATED link via the Ethernet, as shown in Figure 27. /12/

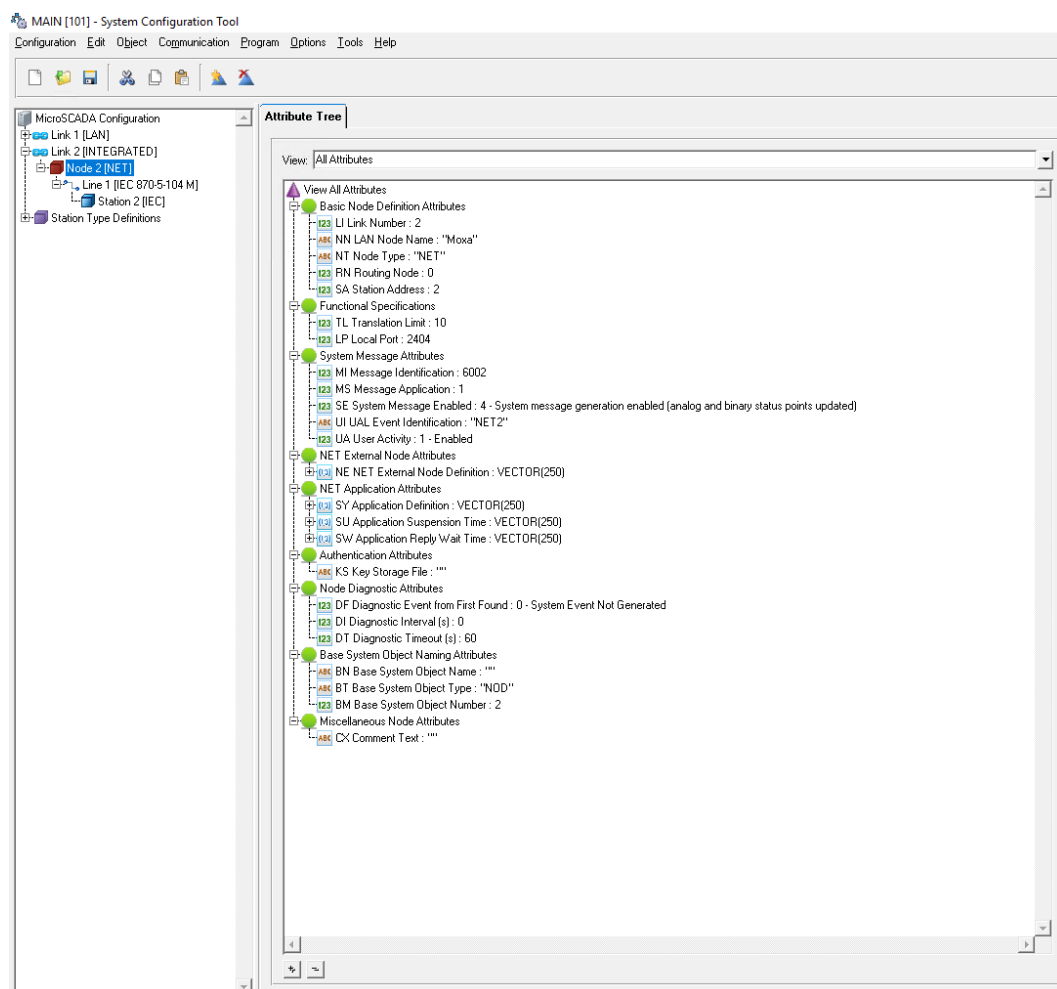

**Figure 27.** Link 2 (INTEGRATED).

NET instance contains a set of system which specify the existence and the usage of the communication line and the station object. In IEC 60870-5-104, there are two kinds of addresses:

- Station address, which is a common address of an ASDU. There can be several common addresses of an ASDU with the same link address.
- Signal address, which is an information object address. This address is unique for each signal with the same common address of an ASDU. /12/

Figure 28 shows that the station object was named as Station 2 and it was connected to Line 1.

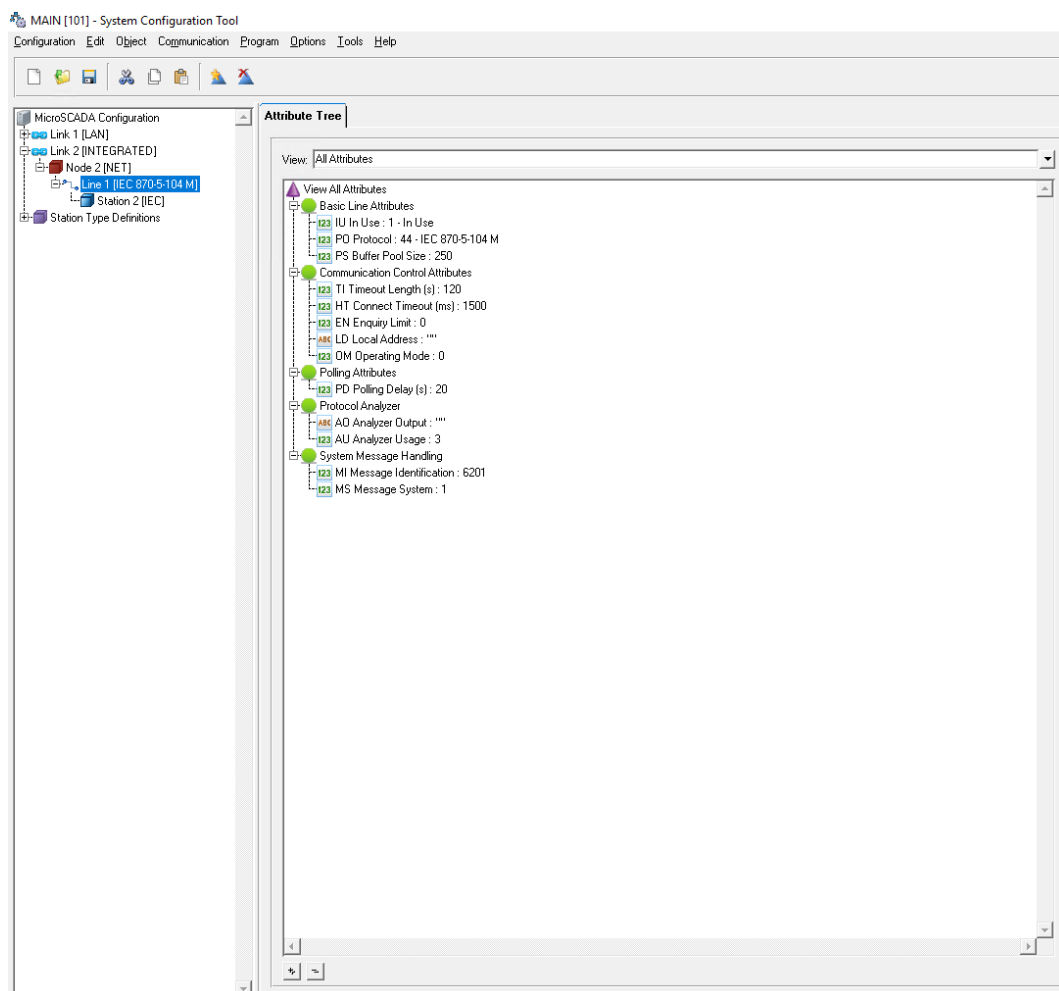

**Figure 28.** Node 2 (NET).

In SYS600 the communication system can be divided into two layers. These layers have a specific functionality and a set of attributes. The possible layers are:

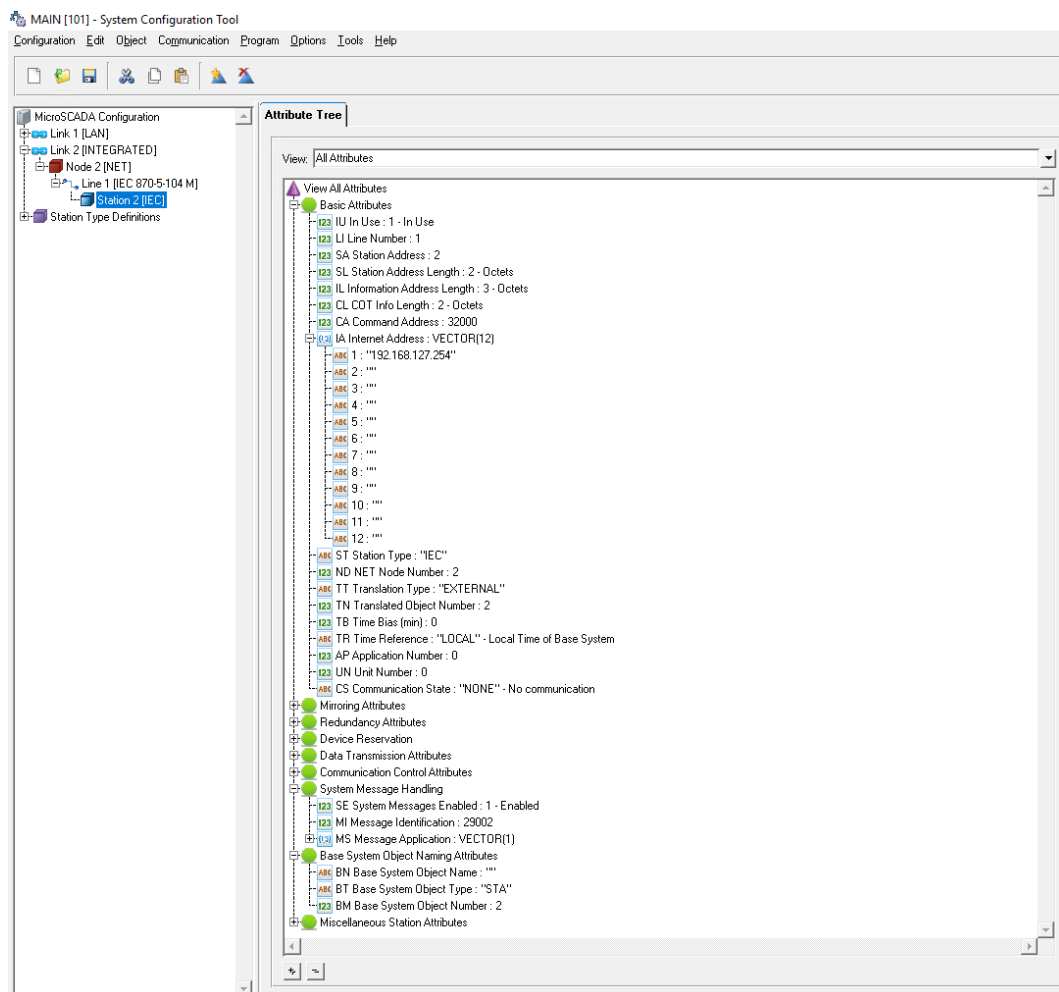

- Line layer
- Station layer. /12/

The line process of a NET unit performs the functions of the line layer. The purpose of the IEC 60870-5-104 Line layer is to send and receive messages to/from devices using the IEC 60870-5-104 protocol. Figure 29 shows the attributes that were used to configure the IEC 60870-5-104 Master Line 1 in SYS600. /12/

**Figure 29.** Line 1 (IEC 60870-5-104 Master).

The base system sees each IEC device as a station object that has been created to a line of a NET unit. Each station works then as a protocol converter that converts data between the internal protocol of SYS600 and the IEC 60870-5-104 protocol. The station object takes care of the application level communication with the slave device. Figure 30 shows the most important attributes that used for configuring the IEC 60870-5-104 Station 2 in SYS600. /12/

**Figure 30.** Station 2 (IEC).

### 4.3.3 SNMP Engineering

SNMP is a protocol for managing and monitoring devices on the IP network. The devices that supported SNMP were the MGate gateway and AFS675 switch. This section gives an example of the configurations which establish the SNMP communication in MGate. The MGate supports the SNMP agent versions V1, V2c and V3 /6/. It was possible to adjust SNMP agent settings in MGate by following the path: System Management > SNMP Agent. The used SNMP agent settings in MGate can be seen in Figure 31.

The screenshot displays the 'SNMP Agent Settings' configuration page. On the left is a 'Main Menu' sidebar with 'SNMP Agent' highlighted. The main content area is titled 'SNMP Agent Settings' and contains a 'Configuration' section. The settings are as follows:

Setting	Value
SNMP	Enable
Contact name	MGate_5114_Test
Read community string	public
Write community string	private
SNMP agent version	V1, V2c
Read-only username	
Read-only authentication mode	Disable
Read-only password	
Read-only privacy mode	Disable
Read-only privacy	
Read/write username	
Read/write authentication mode	Disable
Read/write password	
Read/write privacy mode	Disable
Read/write privacy	

A 'Submit' button is located at the bottom right of the configuration area.

**Figure 31.** SNMP Agent.

The objects are defined in a MIB, which provides a standard presentation of the information /13/. The MGate has a built-in SNMP agent software that supports RFC1213 MIB-1, as seen in Figure 32. /6/

## RFC1213 MIB-II Supported SNMP Variables

System MIB	Interfaces MIB	IP MIB	ICMP MIB
sysDescr	ifNumber	ipForwarding	icmpInMsgs
sysObjectID	ifIndex	ipDefaultTTL	icmpInErrors
sysUpTime	ifDescr	ipInReceives	icmpInDestUnreachs
sysContact	ifType	ipInHdrErrors	icmpInTimeExcds
sysName	ifMtu	ipInAddrErrors	icmpInParmProbs
sysLocation	ifSpeed	ipForwDatagrams	icmpInSrcQuenchs
sysServices	ifPhysAddress	ipInUnknownProtos	icmpInRedirects
	ifAdminStatus	ipInDiscards	icmpInEchos
	ifOperStatus	ipInDelivers	icmpInEchoReps
	ifLastChange	ipOutRequests	icmpInTimestamps
	ifInOctets	ipOutDiscards	icmpTimestampReps
	ifInUcastPkts	ipOutNoRoutes	icmpInAddrMasks
	ifInNUcastPkts	ipReasmTimeout	icmpInAddrMaskReps

**Figure 32.** RFC1213 MIB-II Supported SNMP Variables in MGate. /6/

The MicroSCADA SNMP OPC Server uses the OID identification to request the information from the SNMP agent. The software named as Snpb was used to discover the OID number. The OID is a number structure that is used to identify the signal. In Snpb, the network was scanned on a given IP-range. After the SNMP agent MGate\_5114\_Test was discovered, it was added to the Remote SNMP Agent list. The OID of the MGate's Ethernet port link status was found in IfOperStatus, as shown in Figure 33. After the Walk function was done, the Query Results sub-windows gave the stats of Ethernet ports 1 and 2. /13/

The screenshot shows the SnmpB application interface. The MIB Tree is expanded to show the hierarchy: interfaces > ifTable > ifEntry > ifOperStatus. The Node Info panel for ifOperStatus is displayed below, with the following details:

Name:	ifOperStatus
Oid:	1.3.6.1.2.1.2.1.8
Composed Type:	Enumeration
Base Type:	ENUM
Status:	current
Access:	read-only
Kind:	Column
SMI Type:	OBJECT-TYPE
Value List:	up (1) down (2) testing (3) unknown (4) dormant (5) notPresent (6) lowerLayerDown (7)
Module:	IF-MIB
Description:	The current operational state of the interface. The testing(3) state indicates that no operational packets can be passed. If ifAdminStatus is down(2) then ifOperStatus should be down(2). If ifAdminStatus is changed to up(1) then ifOperStatus should change to up(1) if the interface is ready to transmit and receive network traffic; it should change to dormant(5) if the interface is waiting for external actions (such as a serial line waiting for an incoming connection); it should remain in the down(2) state if and only if there is a fault that prevents it from going to the up(1) state; it should remain in the notPresent(6) state if the interface has missing (typically, hardware) components.

The Query Results panel shows the following output:

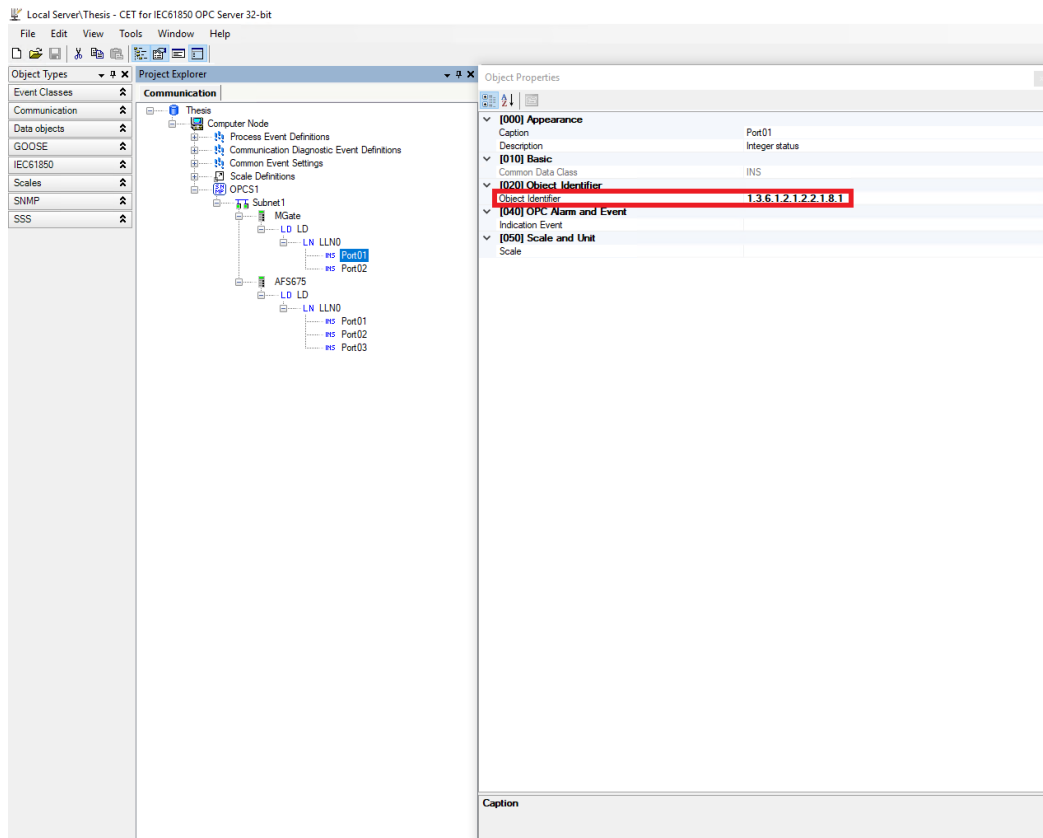

```

-----SNMP query started-----
1: ifOperStatus.1 up(1)
2: ifOperStatus.2 up(1)

```

**Figure 33.** MIB Tree in SnmpB.

A new project was created in the Communication Engineering Tool. OPC Server for SNMP (OPCS1), Subnetwork (Subnet1) and SNMP IED objects (MGate and AFS675) were added under the Computer Node. After the LD was added to tree, the INS data objects were created under the LLN0. These were named as Port01 and Port02. In the Object Properties windows, the last digit was added in Object Identifier to point to a specific port, as seen in Figure 34. /13/

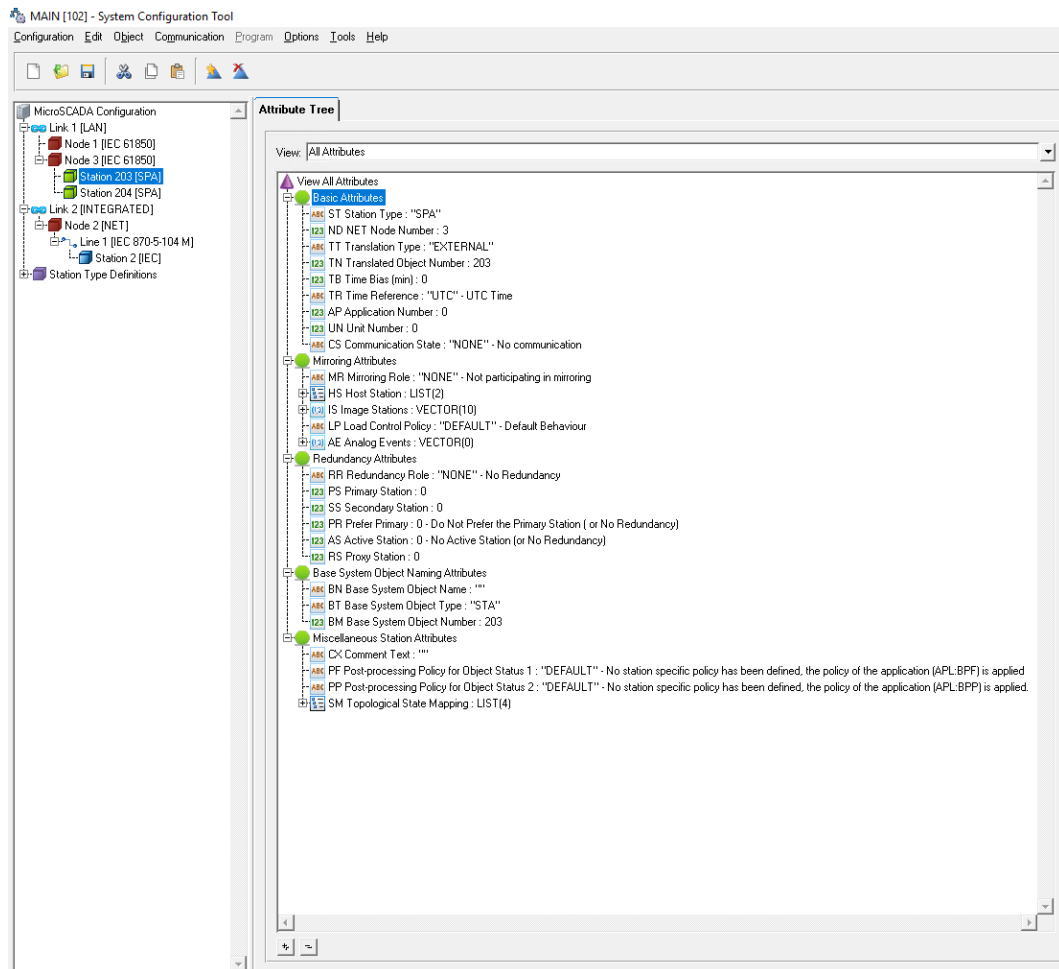

**Figure 34.** CET for IEC61850 OPC Server (Object Properties of the Port01).

In the SNMP OPC DA Client Configuration Tool, the stations 203 and 204 were created under the CPI Node. The connected OPC items were added under the Group\_1 and Ground\_2, as Figure 35 presents. After the configuration, the configuration file was named as SNMP.ini and saved to a specific path.

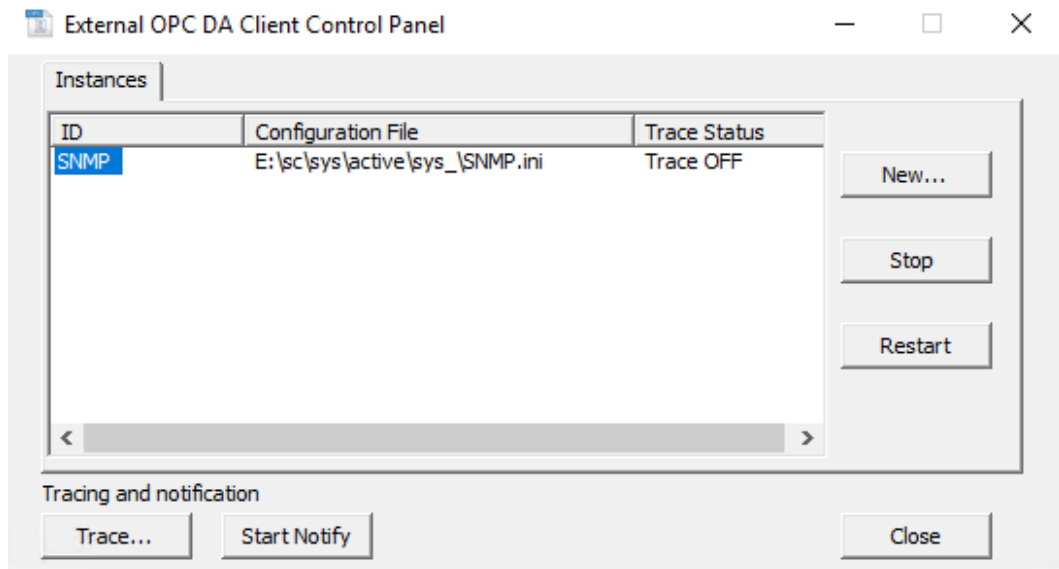

**Figure 35.** SNMP OPC DA Client Configuration Tool (Connected OPC items).

In the SYS600 System Configuration Tool the Node 3 (IEC61850) was created under the Link 1 (LAN). As seen in Figure 36, the added stations were the same ones as the earlier created stations 203 and 204 in SNMP OPC DA Client Configuration Tool.

**Figure 36.** System Configuration Tool (Stations 203 and 204).

The command procedures in SYS600 were created to start and stop DA Client communication. As shown in Figure 37, the configuration file SNMP.ini started automatically after the SYS600 has started.

**Figure 37.** External OPC DA Client Control Panel.

#### 4.3.4 SYS600 Process Object Database

The process object database in SYS600 should contain a process object whose value changes after the process data is received from the process device. The data types and the addresses of the data points used by each process device needed to be identified to create a process object database. The process objects were created for stations 2, 203 and 204. Figure 38 presents the process object database of the station 2. /12/

LN	OK	[UN]	[DA]/M	[OB]/EH	DI	OK	ST

### 4.3.5 Testing the Connection and Configuration

As seen in Figures 40 and 41, the Modbus RTU/ASCII Diagnostics and the IEC 60870-5-104 Server Diagnostics webpages in MGate provided the needed status information. In these webpages it was possible to verify that the data or packet counters were running and thus to make sure that the communications were running smoothly. These webpages can be founded, when following the path: System Monitoring > Protocol Status > Modbus RTU/ASCII Diagnostics or IEC 60870-5-104 Server Diagnostics.

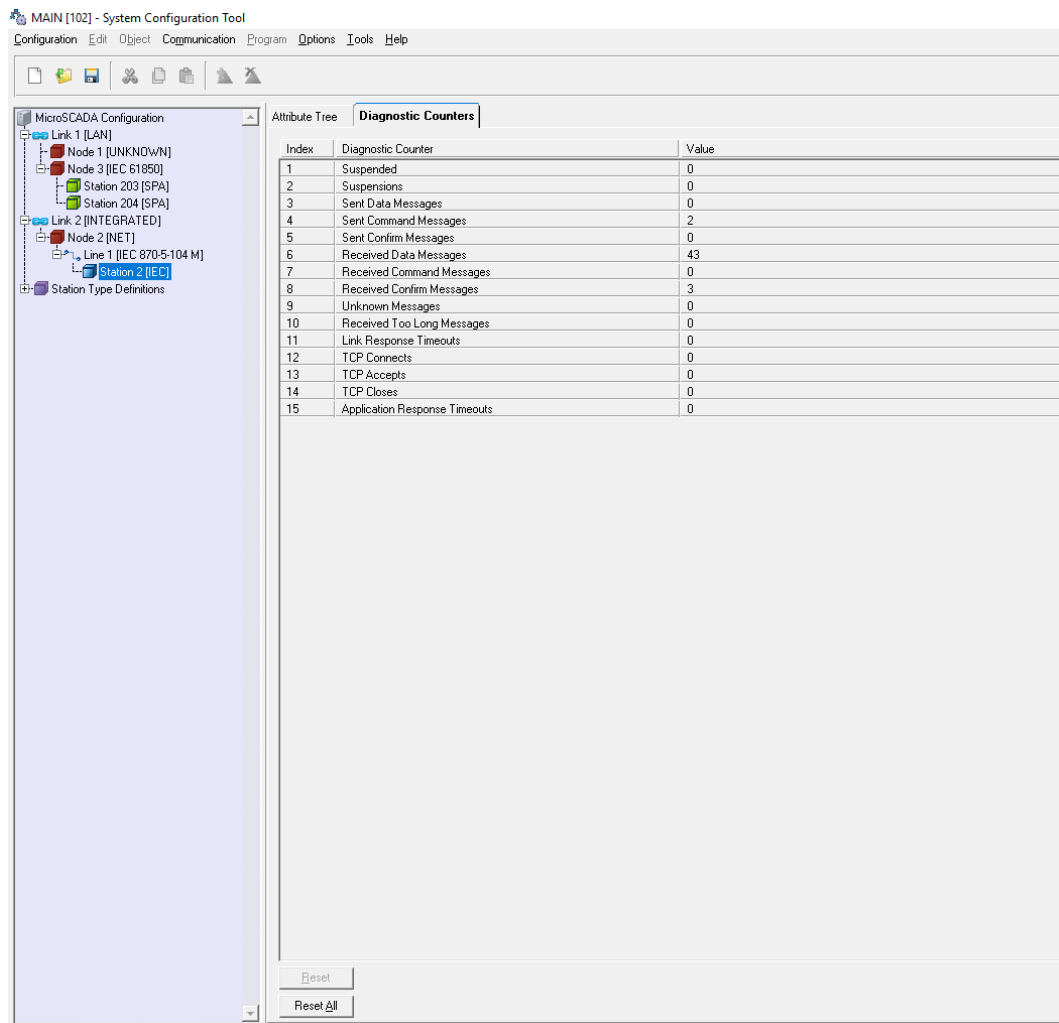

❁ Modbus RTU/ASCII Diagnostics		
<input checked="" type="checkbox"/> Auto refresh		
Category	Item	Value

Error Message	OK

**Figure 41.** IEC 60870-5-104 Server Diagnostics.

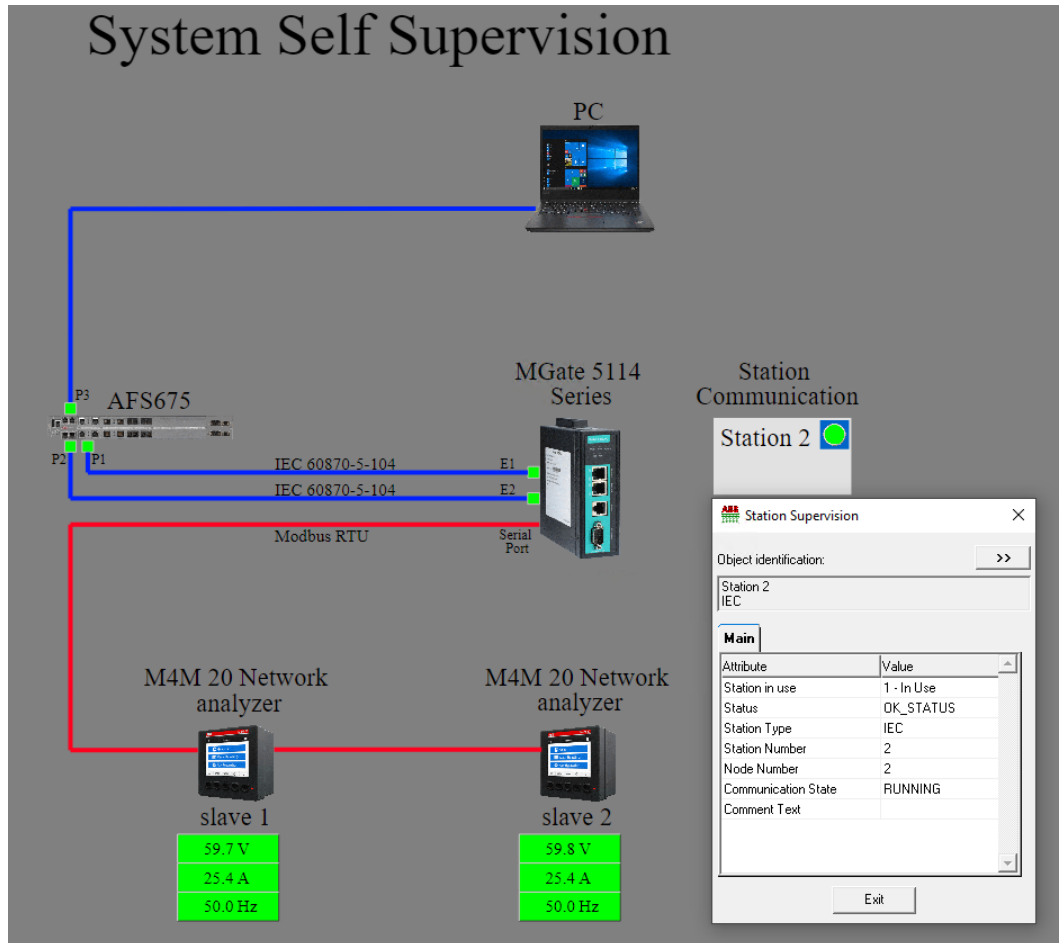

In the SYS600 System Configuration Tool, the diagnostic counter was indicating the number of received and sent messages, when the communication between the master and slave was running. Figure 42 presents the station 2 in online mode.

**Figure 42.** Station 2 in online mode.

In SYS600, the System Self Supervision display was created by using Display Builder. Its purpose in the MicroSCADA system is to supervise and monitor the system itself. The installation of System Self Supervision functionality was enabled from the Tools menu of the System Configuration Tool. The supervised SNMP devices were the MGate 5114 Series and AFS675 port statuses. As shown in Figure 43, the System Self Supervision display also contained the information of the station 2 communication and process display devices measurement panels. Green

colour in measurement panels, communication ports and station 2 indication mean status ok. The communication of the station 2 was in running state. /14/

**Figure 43.** System Self Supervision (No malfunction situations).

Figure 44 shows that process object Active power L1 value was 1.52 kilowatts.

**Figure 44.** The value of the process object Active power L1.

Figure 45 shows the same measured value in M4M 20 Network analyzer slave 1.

**Figure 45.** Active power L1 in M4M 20 Network analyzer slave 1.

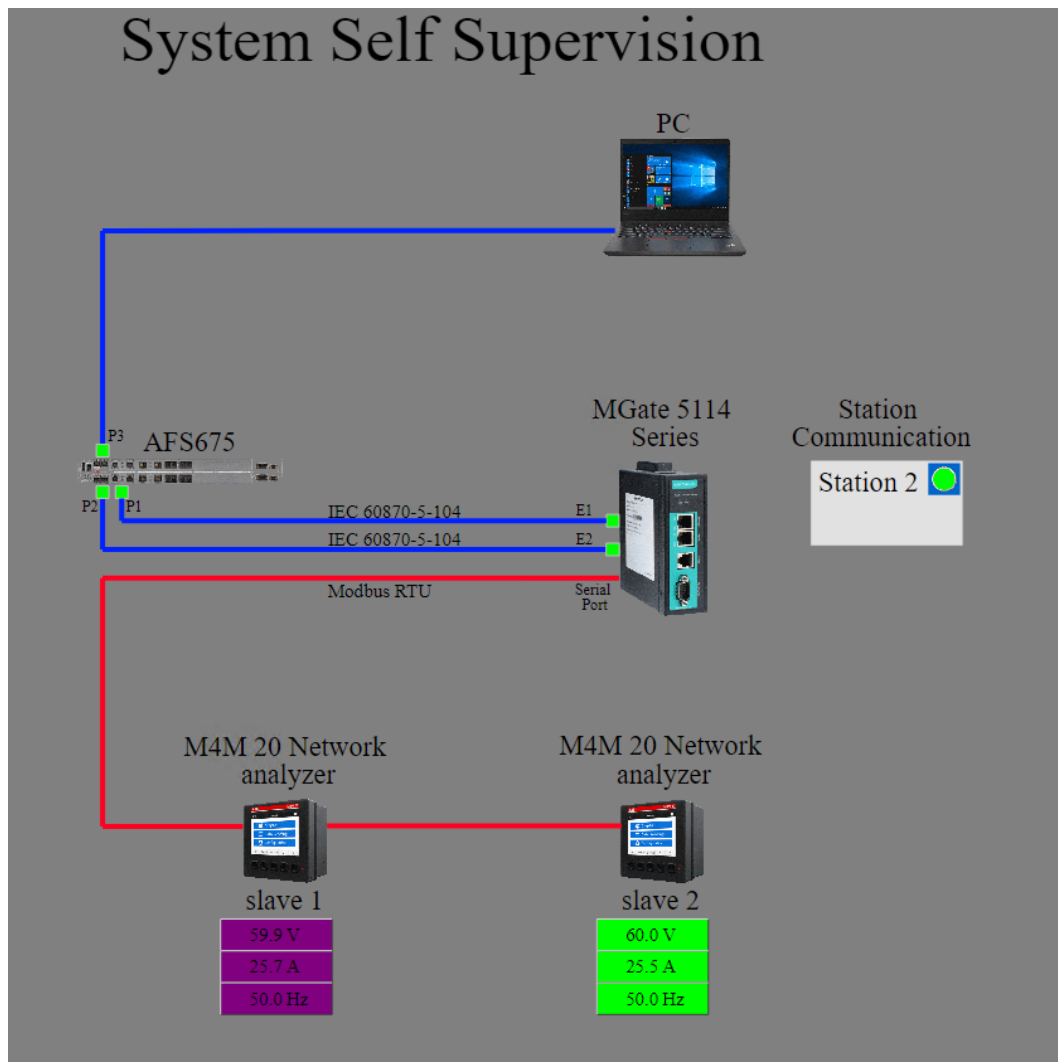

As a conclusion we can state that MGate is also capable to read multiple Modbus registers without any performance problems.

#### **4.4 MGate 5114 Series Performance in a Malfunction Situations**

Typically, the infrastructure SCADA system includes a large numbers of various energy meters. Different types of the malfunction situations must be noticed and informed to the SCADA system. When an error occurs in the SCADA system, finding the root cause can be a difficult and complex task. The MGate provides different types of useful troubleshooting tools, which are helpful in case of possible malfunction situations. The following simulated malfunction situations are the typical fault situations in infrastructure SCADA projects.

##### **4.4.1 Malfunction Situation in M4M 20 Network Analyzer Slave 1**

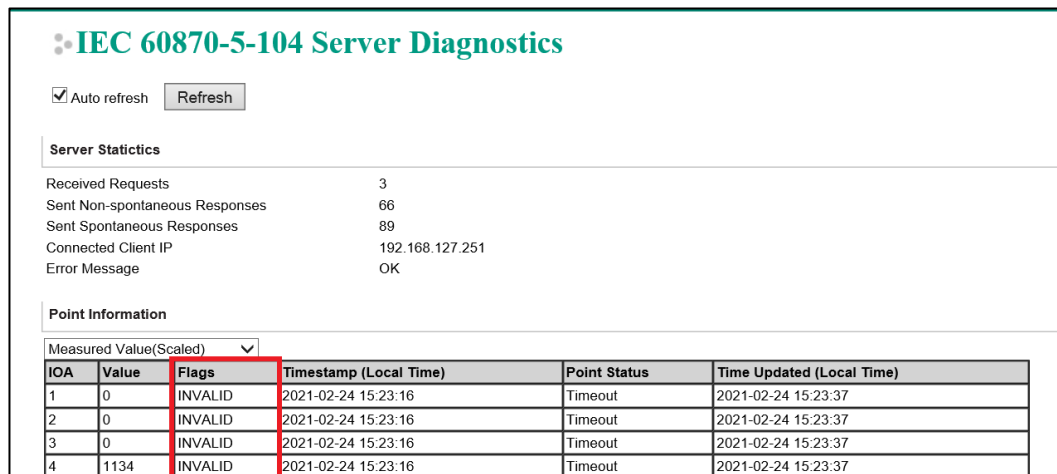

The first simulated test was the malfunction situation of the M4M 20 Network analyzer slave 1. The aim of this section was to ensure that the performance of the data collection of the remaining analyzer is not be disturbed even if the other analyzer communication fails due to power error. Figure 46 presents the System Self Supervision display when the M4M 20 slave 1 is not responding and thus its measurement statuses are in unknown state. Otherwise the statuses of the system are in ok status.

**Figure 46.** System Self Supervision (M4M 20 slave 1 is not responding).

The Alarm Display in SYS600 shows a summary of the present alarm situation of the supervised system. As shown in Figure 47, the device M4MS1 indicated alarm status. Usually, each alarm is presented as an alarm text row, which describes the cause of the alarm in the process. In this case the alarm text row has a time stamp, an object identification, an object text and text indicating the alarm status.

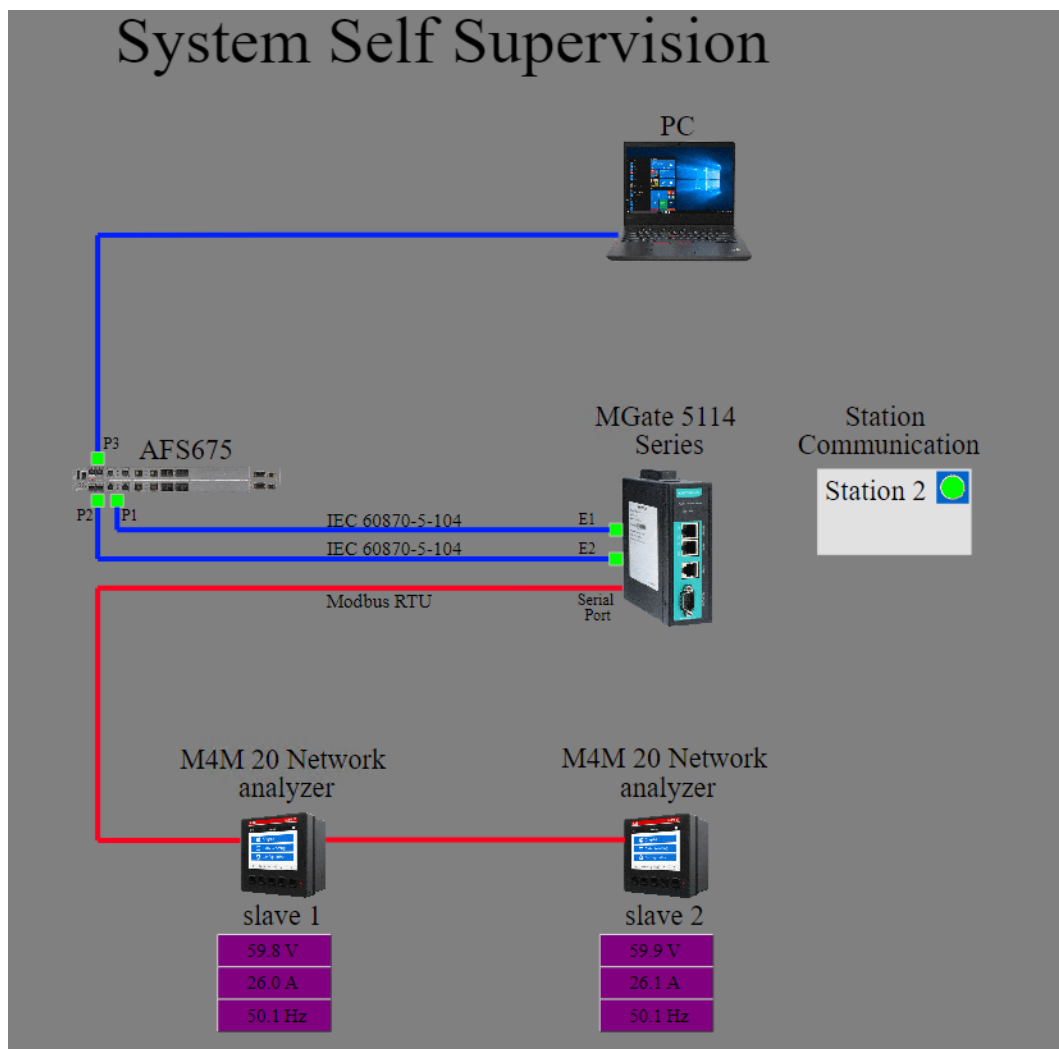

**Figure 48.** IEC 60870-5-104 Server Diagnostics (Flags are turned INVALID).

As a conclusion of the first simulated fault situation we can state that the performance of the data collection of the remaining analyzer continues even if the other analyzer was not responding. The unnormal operation of the M4M 20 slave 1 was seen in System Self Supervision display and informed to the Alarm Display in SYS600. The malfunction of the other analyzer was also seen in MGate's diagnostics tool.

#### 4.4.2 Malfunction Situation in Both M4M 20 Network Analyzers

The second simulated test was the malfunction situation, when the both M4M 20 Network analyzer slaves were powered off. The aim of this section was to ensure that the MGate continues to respond to SCADA and its normal operation is not disturbed even if the communication of the analyzers fails due to power error. Figure 49 presents the System Self Supervision display when the M4M 20 slaves are not responding and thus the measurement statuses of the analyzers are in unknown state. Otherwise the system is in ok status.

**Figure 49.** System Self Supervision (M4M 20 slaves are not responding).

12	59.134	Send	1	3	01 03 89 11 00 08 3E 55
13	64.133	Send	1	3	01 03 89 11 00 08 3E 55

**Figure 51.** Traffic (Maximum retry=1, response timeout=5000 milliseconds).

As a conclusion of the second simulated fault situation we can state that the MGate continues to respond to the SCADA and its normal operation is not disturbed even if the M4M 20 slaves are not responding. The unnormal operation of the analyzers was informed to the SCADA and it was also seen in MGate's traffic monitoring tool.

#### 4.4.3 Malfunction Situation in MGate 5114 Series

The third simulated situation was the malfunction of the MGate 5114 Series. The aim of this section was to ensure that the abnormal situation of the MGate is informed to the SCADA and it also activates the suitable alarms. When MGate was powered off, this caused different types of alarms. As seen in Figure 52, the ports P1 and P2 are in alarm state, whereas the ports E1 and E2 are in unknown state. The communication state of the station 2 is in suspended state. The measurement panels of the field devices are in unknown state.

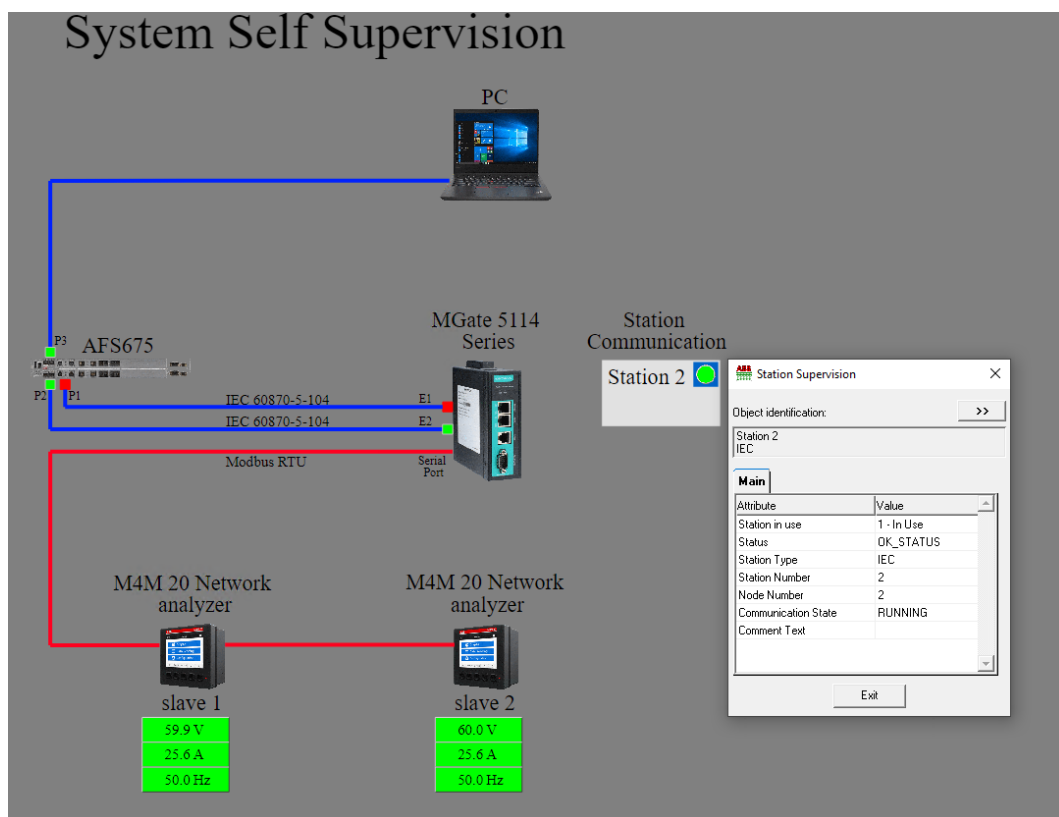

**Figure 52.** System Self Supervision (MGate 5114 Series is not responding).

Figure 53 presents the alarms, which were activated when the MGate was powered off.

#### 4.4.4 Malfunction Situation of the IEC 60870-5-104 Primary Line

The fourth and the last simulated situation was the malfunction of the IEC 60870-5-104 primary line. The aim of this section was to verify that the connection is transferred to the IEC-60870-5-104 secondary line after the primary line was disconnected. This should be possible with minimal connection timeout. Figure 54 shows that the alarms of the ports P1 and E1 were activated, when the communication of the IEC 104 primary line failed.

**Figure 54.** System Self Supervision (IEC 60870-5-104 Primary Line Failed).

## 5 CONCLUSIONS

This thesis gives an overall picture of how to configure the MGate 5114 Series gateway device by using the Moxa dedicated tool and a practical example of how to establish the system with MicroSCADA, including database and communication.

The other aim of this thesis was to find out more information about the energy metering applications and this purpose was met in this thesis. The used M4M 20 Network analyzers is one of the examples of used energy metering devices in infrastructure SCADA projects. The test results show that this kinds of analyzers are capable to interface with MicroSCADA.

One of the best features in MGate is that it provides a useful configuration tool. The gateway device provides various troubleshooting tools, which are helpful in case of a possible malfunction situation of the system. The automatic mapping arrangement makes engineers' work easier. The addresses should be double-checked that they are mapped right in cases where the automatic mapping arrangement is used. The performance of the MGate is reliable when reading single or multiple type of Modbus registers. Based on the testing results of this thesis, the MGate has the needed performance and reasonable features so that it is possible to use the gateway device in the future infrastructure SCADA projects.

It would have been interesting to test performance of MGate in a larger system, but due to the given scope of this thesis and test environment limits, it was not possible. The performance of the gateway device in part of a system, where there are multiple and different types of energy meters would be ideal to test in future. This could be a possible topic for a thesis in the future.
